

Trie

What is Trie data
structure?

known as a prefix tree, that is used to store a dynamic set of strings where the keys usually represent sequences of characters. This comes from the word "retrieval" because it provides a way to quickly retrieve data based on keys.

Why we learn this

ds?

Gain Deeper
understanding on
trees.

Efficiency in string operations

Auto completion
and searching
algorithm.

Data Storage and Retrieval

Properties of tries

Node structures

- character
- end of word
- connected by edge.

root node is always

empty

Child nodes :-

represent the next

character of its parent

node.

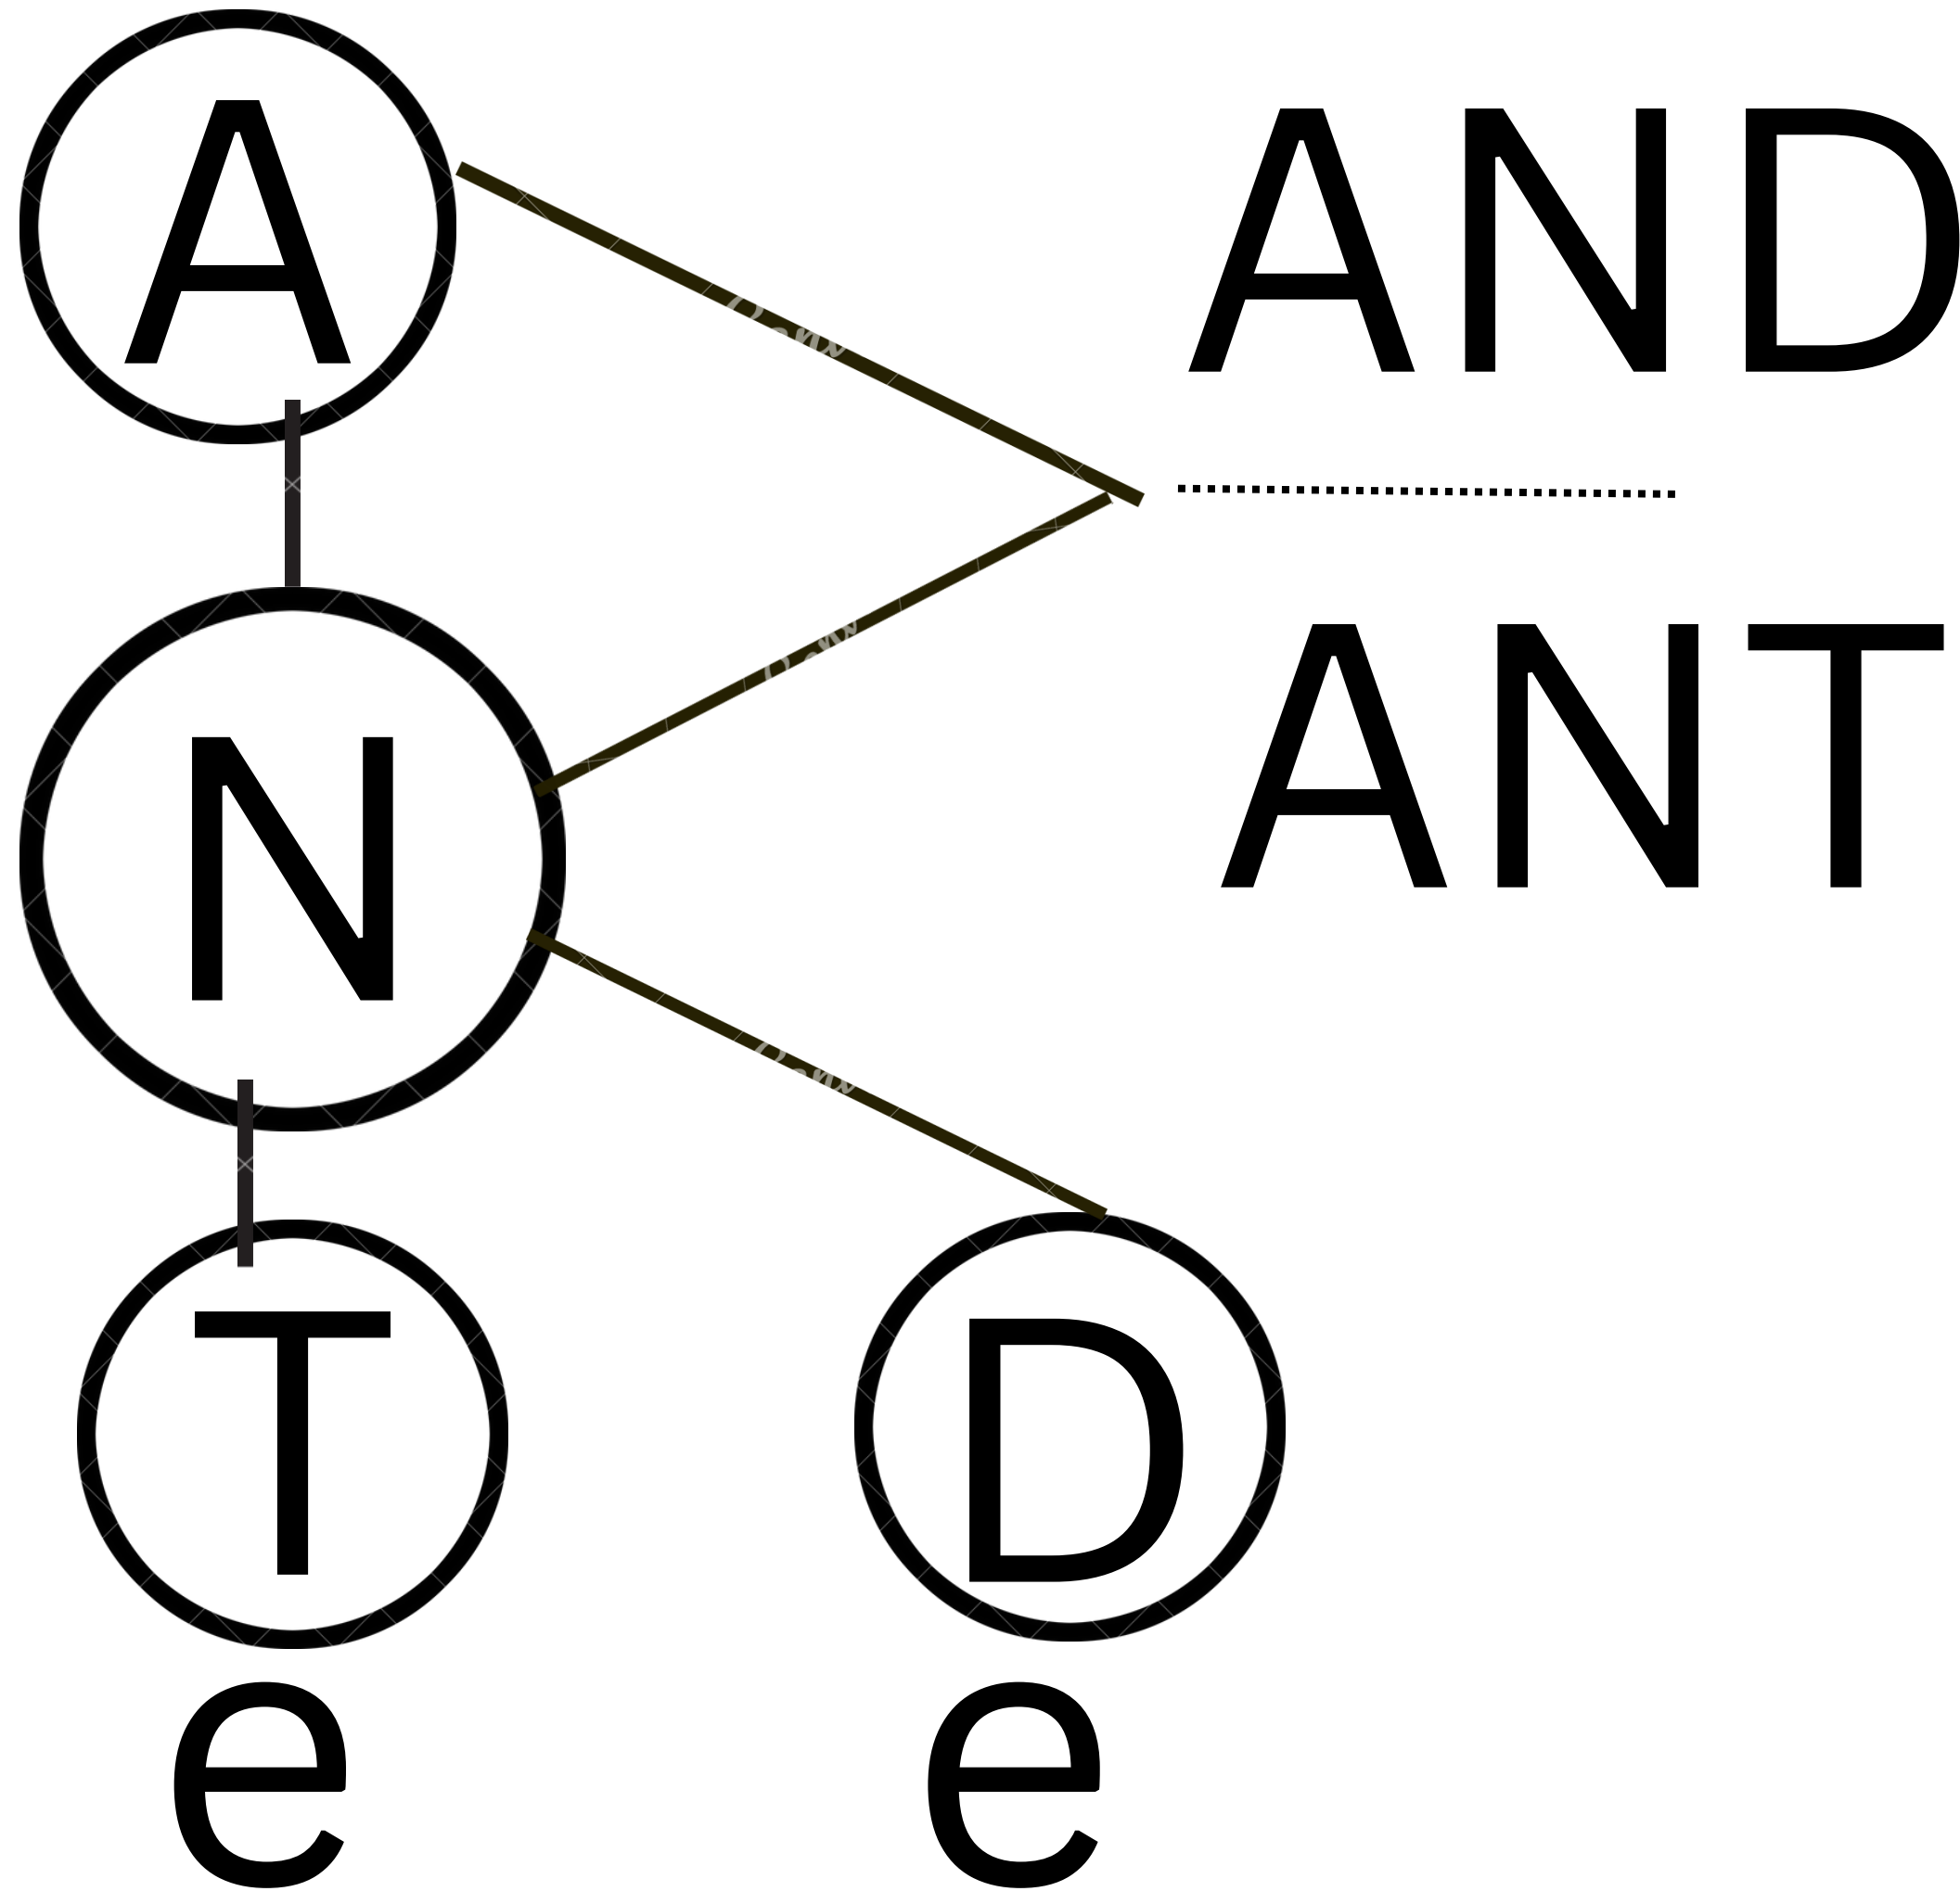

.....
end of the word

when find a character end of a
word then consider a word
otherwise each node contains as a
prefix node.

.....
end of the word

Here A and N are prefix nodes

every 1st char is added
with root node.

Now, see an
example of
insertion at here.

Lets try to addd Life
at here.

Now, try to search
from here.

Algorithm

Algorithm

Algorithm

Lets try to delete
some variable from
here.

In case of deletion we mainly not delete a string. we mainly delete end character of the string as false. And we mainly delete the char's which is not present as a prefix of any string.
